

Backend Assignment

Problem Statement

Build a backend system for an E-Library Management System.

The platform should allow users to interact with a collection of books, think in terms of what a digital library needs to function (managing books, users, borrowing, searching, etc.). In addition, the system should include an AI-powered Book Summary feature, where users can get a generated summary of a book (e.g., based on its title, description, or content).

Beyond these two anchor points, the exact scope, features, and design decisions are intentionally left open-ended.

Responsibilities

This problem statement is deliberately high-level. It is up to you to:

- Decide what entities, features, and workflows make sense for an e-library system
- Decide how the AI summary feature should work and where it fits into the system
- Identify edge cases, constraints, and real-world considerations we haven't spelled out
- Add as many additional features as you can think of, beyond the minimum implied above
- Regardless of how many features you build, your code must be modular, structured & maintainable.

We're not looking for a system that checks a fixed list of boxes. We're looking at how you think, what you prioritize, and how far you push a vague requirement into a well-reasoned, working product.

Tech Stack

- Node.js, Python
